Docker Tutorial

Another Todo App

Awesome Compose

Docker vulnerability

Generally fall into 3 categories:

- Outdated container runtime or engine software (breakouts)
- Vulnerable 3rd-party application dependencies (image & libs)
- System misconfigurations (`:latest` tag, mount `/var/run/docker.sock`)

Remediation & Practice

- Integrate (automated) docker image security scanners
 - `trivy`, Docker Scout
 - [Visscan Project](#)

Docker compose scaling

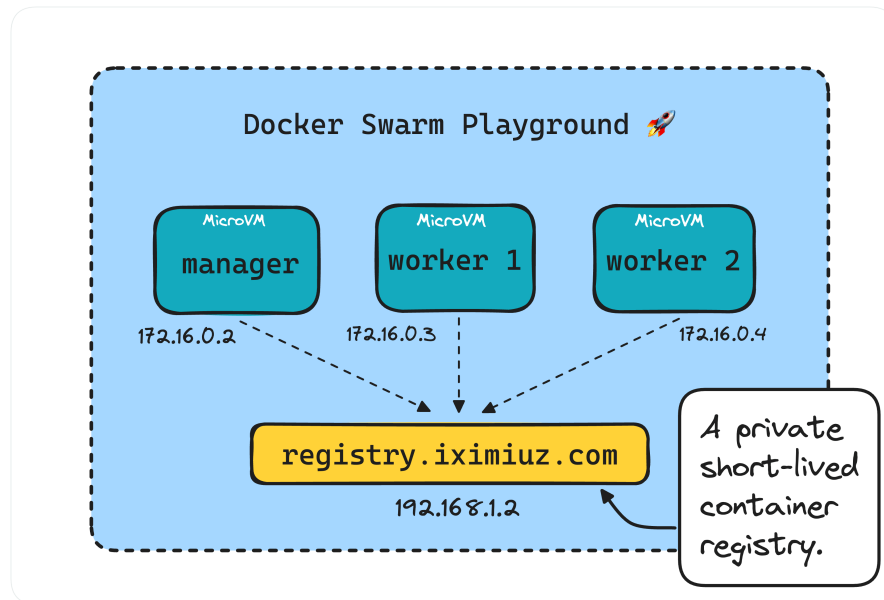

- The process of horizontally expanding/shrinking your app by running **multiple instances** of the same containerized service
- By default, `docker compose` spins up exactly one container per service

Docker compose scaling - How to

- No **static host ports** (like `"8080:80"`)
 - Instead expose only container port (`"80"`)
 - Docker assigns random host ports automatically
- No **custom container names** (like `container_name: my_app`)
 - Docker manages names by adding suffixes (`web-1` , `web-2`) when scaling
- Requires a **load balancer** (`nginx` , `caddy` , `traefik`)

Docker Swarm

- Docker's native **container orchestration tool**
- Manages a cluster of multiple Docker engines/hosts as a single virtual system
 - Control deployment, scaling, networking, HA
